Chapter 1

Introduction

1.1 Thesis Objective

The thesis aims at giving an overview of time series analysis methods for irregularly sampled data.

The standard time series analysis methods usually assume discrete equispaced time and introductory textbooks on time series analysis either completely omit the irregularly spaced case or they only dedicate a very small section to continuous time models or to state-space models with missing observations ([Brockwell and Davis](#), [Brockwell and Davis](#), [Cryer and Chan](#), [Chatfield](#)).

I will thereafter present the most important concepts and what I have identified to be the basic methods for the analysis of irregularly spaced time series.

The topic is motivated by a "real world" problem from medicine. The problem at hand is the one of extracting time series characteristics from a dataset featuring blood pressure (BP) measurements sampled at irregularly spaced time points. High BP is known to be a risk factor for cardiovascular disease. A person's BP level is generally summarized using the average BP value over available measurements within a given time range. A novel monitoring device already allows to collect BP estimates round the clock. The device is collecting photoplethysmography (PPG) signals and converting them into BP measurements. Typically, the system will yield approximately 1.5 BP measurements per hour, but depending on the quality of the PPG signal and some additional external factors, this sampling frequency can widely vary and the expected range lies roughly between 0 and 5 measurements per hour. Having good estimates of the true BP values at any, potentially not observed, time would allow for a better estimation of the person's cardiovascular risk, and enable the development of novel valuable metrics. The thesis will focus on a set of time series characteristics, which have been considered most relevant for estimating the person's cardiovascular risk. The characteristics of interest are:

- the mean function of the BP time series
- the one-week mean BP value
- any "long-term" trends
- characteristics of the circadian cycle, such as the mean day and night BP

Besides the point estimates also their CIs are of interest. Importantly, the CI should be able to capture the uncertainty due to the lack of data in the proximity of the point of prediction. This implies, that the width of the CI intervals around the mean function will not be constant over time but depend, among other factors, on how much data is available in the proximity of a given time point. The described endpoints are all based on prediction at the not observed passed time points however not on forecasting at new time points in the future. Hence, the thesis will only focus on the task of reconstructing BP values between the first and last time point in the dataset.

This "real world" problem will serve as a running example throughout the Thesis. Although the topic is motivated by a real dataset we will restrict ourselves to simulated data, which will mimic the most important characteristics of BP time series data.

1.2 Thesis Outline

Chapter 2

Characteristics of Time Series

A **time series** $(x_t : t \in T_0)$ is a collection of observations x_t , each one being recorded at a specific time t . T_0 is the set of times at which observations are made. In case of discrete time series T_0 is a discrete set, e.g. for the equispaced case $T_0 = \{1, 2, \dots, T\}$ and for the unequally spaced case $T_0 = \{t_1, t_2, \dots, t_n\}$ with $t_1 < t_2 < \dots < t_n$. For continuous time series T_0 is an interval, e.g. $T_0 = (0, T]$.

A **time series model** for the observed data $(x_t : t \in T_0)$ is specified by the collection of random variables $(X_t : t \in T_0)$ of which $(x_t : t \in T_0)$ is thought to be a realization. Alternatively the time series model can also be considered a random function $f : T_0 \rightarrow \mathbb{R}$.

Throughout the thesis the term time series is used both refer to the data and the process from which it is generated.

Chapter 3

Time Series Decomposition and Regression

As most time series, the mean function of the BP time series is not constant in time and hence it is not stationary. One can try to decompose the time series $Y(t)$ into a deterministic component, the mean function $\mu(t)$ and a zero mean stationary process $E(t)$. This can be expressed in the form of a regression problem:

$$Y(t) = \mu(t) + E(t)$$

The decomposition allows to extract a stationary component $E(t)$, for which we can find a probabilistic model using the theory of such stationary time series processes. The idea is to then use this model in combination with an estimate of $\mu(t)$ to obtain a probability distribution of Y^* at some time t^* . Hence time series decomposition comes for free in regression analysis and we start with estimation of the deterministic component $\mu(t)$ which might be an arbitrary function of t .

3.1 Linear Regression

Based on the knowledge we have about the system we might restrict ourselves to a family of functions for $\mu(t)$. An obvious choice for the BP time series is the family of functions featuring a linear trend with an additive seasonal component. If the seasonal component is represented by a cosine of the form $\alpha \cos(2\pi ft - \phi)$ with phase shift ϕ and known frequency f , we get the following model for the BP time series $Y(t)$:

$$Y(t) = \beta_0 + \beta_1 t + \beta_2 \cos(2\pi ft) + \beta_3 \sin(2\pi ft) + E(t),$$

where based on the trigonometric angle sum identities we know that $\beta_2 = \alpha \cos(\phi)$ and $\beta_3 = \alpha \sin(\phi)$.

If we assume BP observations at potentially unequally spaced time points $t_1, t_2 \dots t_n$ and $t_1 < t_2 < \dots t_n$, we can write in matrix notation:

$$\mathbf{Y} = X\beta + \mathbf{E}$$

Where $\mathbf{Y} = [Y_{t_1}, \dots, Y_{t_n}]^\top$ is the observed time series, $X = [x_{t_1}, \dots, x_{t_n}]^\top \in \mathbb{R}^{n \times 4}$ is the design matrix with i -th row, written as a column vector $x_{t_i} = [1, t_i, \cos(2\pi f t_i), \sin(2\pi f t_i)]^\top$ and $\mathbf{E} = [E_{t_1}, \dots, E_{t_n}]^\top$ the zero-mean stationary time series, which we will call errors.

We can use ordinary least squares to find unbiased and asymptotically normal estimates $\hat{\beta}_{OLS} = (X^\top X)^{-1} X^\top Y$ for the regression coefficients β , without the requirement of regularly spaced data points or uncorrelated errors E_{t_1}, \dots, E_{t_n} (White). In the case of uncorrelated errors with constant variance σ^2 we have $\text{Var}(\mathbf{E}) = \sigma^2 I_n$ and an unbiased and consistent estimator for $\Psi = \text{Var}(\hat{\beta}_{OLS})$ is given by:

$$\hat{\Psi} = \hat{\sigma}^2 (X^\top X)^{-1}$$

where $\hat{\sigma}^2 = \frac{1}{n-p} \sum_{i=1}^n (y_{t_i} - x_{t_i}^\top \hat{\beta}_{OLS})^2$ and $p = 4$ in our example

Since \mathbf{E} is a time series, the assumption of uncorrelated errors is usually violated and the covariance matrix $\hat{\Psi}$ is thus no longer unbiased (Brockwell and Davis).

3.2 Regression with Correlated Errors

The argument presented in this section is based on the textbook of Brockwell and Davis.

If the covariance matrix of the errors $\text{Var}(\mathbf{E}) = \Sigma$ is known, we can use generalized least squares to obtain a unbiased, consistent and efficient coefficient estimate:

$$\hat{\beta}_{GLS} = (X^\top \Sigma^{-1} X)^{-1} X^\top \Sigma^{-1} Y$$

with unbiased and consistent covariance matrix estimate:

$$\text{Var}(\hat{\beta}_{GLS}) = (X^\top \Sigma^{-1} X)^{-1}$$

If Σ is unknown one can exploit the knowledge we have about the stationary time series process \mathbf{E} to estimate it. The following subsections will present two approaches to estimate Σ , β and its covariance matrix. Both methods assume an ARMA(p,q) process for \mathbf{E} and equispaced time points, hence $\mathbf{E} = (E_t : t \in \{1, 2, \dots, n\})$ and:

$$\Phi(B)E_t = \Theta(B)W_t, \text{ where } W_t \sim WN(0, \sigma_w^2)$$

3.2.1 Maximum-Likelihood Estimation

If we additionally assume $W_t \sim N(0, \sigma_w^2)$, we can simultaneously estimate the regression coefficients and Σ by maximizing the Gaussian likelihood:

$$L(\beta, \phi, \theta, \sigma_w^2) = (2\pi)^{-\frac{n}{2}} (\det(\Sigma_n))^{-\frac{1}{2}} \exp\left(-\frac{1}{2} (\mathbf{Y} - X\beta)^\top \Sigma_n^{-1} (\mathbf{Y} - X\beta)\right)$$

Where the covariance matrix $\Sigma_n(\theta, \phi, \sigma_w^2)$ is parametrized by the coefficients θ, ϕ, σ_w^2 , which define the ARMA process assumed for $(E_t : t \in \{1, 2, \dots, n\})$. Assuming an ARMA(2,3) process we can implement this approach in R using the nlme library (Box, Jenkins, and Reinsel) :

```
library(nlme)
cs <- corARMA(from = ~t, p=2, q=3)
fit.gls <- gls(y ~ t + cos(2 * pi * f * t) + sin(2 * pi * f * t), corr=cs)
```

3.2.2 Sandwich Estimation

The second approach is to fit an OLS regression first and correct the estimated covariance matrix of the regression coefficients Ψ with a sandwich estimator. In the presence of autocorrelation one usually estimates $\Phi = \frac{1}{n}X^\top \Sigma X$, the covariance matrix of the scores or estimating functions $V_i(\beta) = x_{t_i}(y_{t_i} - x_{t_i}^\top \beta)$, which can then be used to derive Ψ :

$$\Psi = \text{Var}(\hat{\beta}_{OLS}) = (X^\top X)^{-1} X^\top \Sigma X (X^\top X)^{-1} = \left(\frac{1}{n}X^\top X\right)^{-1} \frac{1}{n} \Phi \left(\frac{1}{n}X^\top X\right)^{-1} \quad (3.2.2.1)$$

The general form of the estimators for Φ is:

$$\hat{\Phi} = \frac{1}{n} \sum_{i,j=1}^n w_{|i-j|} \hat{V}_i \hat{V}_j^\top \quad (3.2.2.2)$$

where $w = [w_0, \dots, w_{n-1}]^\top$ is a weight vector and $\hat{V}_i = V_i(\hat{\beta}_{OLS})$.

Plugging $\hat{\Phi}$ into the equation 3.2.2.1 one obtains the heteroskedasticity and autocorrelation consistent (HAC) covariance estimate $\hat{\Psi}_{HAC}$.

Newey and West, Andrews and others have suggested different approaches for calculating the weights w . They all yield decreasing weights with increasing lag $l = |i - j|$. The R sandwich package implements some of these methods to estimate $\hat{\Psi}_{HAC}$. An introduction to the sandwich package and how it can be used for inference is described by Zeileis.

3.2.3 Extension to Irregularly Spaced Time Series

Although literature and "ready to use" implementations only exist for the equispaced case, both of the approaches described above could probably be extended to the case of irregularly spaced time series. For the Maximum-Likelihood approach the parametrization of the covariance matrix Σ_n as described in 3.2.1 would need to be adapted, such that the covariance of the errors at different time points depends on the actual time difference rather than the lag. Similarly for the sandwich estimator, the weights in 3.2.2.2 should depend on the time difference rather than on the lag.

3.2.4 Confidence Intervals for the Mean Function

The objective, as described in the introduction, is not only to estimate the mean function $\mu(t)$ of the time BP time series but also to find confidence intervals for it. The model for the BP time series described in 3.1 has the following mean function:

$$\mu(t) = x_t^\top \beta$$

with $x_t = [1, t, \cos(2\pi ft), \sin(2\pi ft)]^\top$

Hence, we may also write $\mu(x_t)$ and its $1 - \alpha$ confidence interval is:

$$x_t^\top \hat{\beta} \pm qt_{n-p}(1 - \frac{\alpha}{2}) \sqrt{x_t^\top \Psi x_t}$$

where $\Psi = Var(\hat{\beta})$ is the covariance matrix of the estimated regression coefficients and $qt_{n-p}(1 - \frac{\alpha}{2})$ denotes the $1 - \frac{\alpha}{2}$ quantile of the student's t-distribution of $n - p$ degrees of freedom.

As the CI for $\mu(t)$ is based on the variance of the estimated global model parameters Ψ , it cannot adapt to the local observation density. Even if we were able to derive realistic confidence interval for the mean function of the irregularly spaced time series, the uncertainty due to the lack of data in the proximity of a time point can still not be reflected.

Chapter 4

Gaussian Process Regression

We again consider a regression problem of mapping the input x to an output $f(x)$. In order to solve such a problem one usually needs some additional constraints on the $f(x)$. In 3 we restricted ourselves to the class of linear functions. Another approach is to assign a prior probability to every possible function, where higher probabilities are assigned to functions that are assumed to be more likely. Inference in this Bayesian setting is then based on the posterior distribution of these functions given some potentially noisy observations of $f(x)$.

This chapter first provides a definition of a Gaussian Process and then describes how they can be used to solve a regression problem.

4.1 Gaussian Process Definition

A Gaussian process (GP) can be viewed as a gaussian distribution over functions or as an infinite set of random variables representing the values of the function $f(x)$ at location x . The Gaussian process is thus a generalization of the Gaussian distribution and a formal definition is given by [Rasmussen and Williams](#) :

Definition 4.1.0.1 (Gaussian Process). *A Gaussian process is a collection of random variables, any finite number of which have a joint Gaussian distribution.*

As a (multivariate) Gaussian distribution is defined by its mean and covariance matrix, a GP is uniquely identified by its mean $m(x)$ and covariance (kernel) function $k(x, x')$.

We write

$$f(x) \sim GP(m(x), k(x, x'))$$

with

$$\begin{aligned} m(x) &= \mathbb{E}[f(x)] \\ k(x, x') &= \mathbb{E}[(f(x) - m(x))(f(x') - m(x')))] \end{aligned}$$

If we assume X to be the index set or set of possible inputs of f , then there is a random variable $F_x := f(x)$ such that for a set $A \subset X$ with $A = x_1, \dots, x_n$ it holds that:

$$F_A = [F_{x_1}, \dots, F_{x_n}] \sim \mathcal{N}(\mu_A, K_{AA})$$

for

$$K_{AA} = \begin{bmatrix} k(x_1, x_1) & k(x_1, x_2) & \dots & k(x_1, x_n) \\ \vdots & & & \vdots \\ k(x_n, x_1) & k(x_n, x_2) & \dots & k(x_n, x_n) \end{bmatrix} \text{ and } \mu_A = \begin{bmatrix} \mu(x_1) \\ \vdots \\ \mu(x_n) \end{bmatrix} \quad (4.1.0.1)$$

The finite marginals F_{x_1}, \dots, F_{x_n} of the GP thus have a multivariate gaussian distribution. In our running example we consider X to be the time interval $T_0 = [0, T]$ however it could be higher dimensional.

Note that Gaussian processes with finite index sets and hence with joint gaussian distribution is just a specific case of GP. If we assume an ARMA process with gaussian innovations for the blood pressure time series, one can view the time series as collection of normally distributed random variables and are thus dealing with a GP.

If we consider the linear regression case from chapter 3 and assume a prior distribution on the β 's, i.e. $\beta \sim \mathcal{N}(0, I)$ then the predictive distribution over $\mu = X\beta$ is Gaussian:

$$\mu \sim \mathcal{N}(0, XX^\top)$$

and represents a GP with mean function $m(x) = 0$ and kernel function $k(x, x') = x^\top x'$. This special case of gaussian process regression with this specific kernel function is known as bayesian linear regression and will be presented in the next section.

4.2 Gaussian Process Regression

Predictions in the Bayesian regression setting is finding the posterior distribution of $f^* := f(x^*)$ at some input x^* , given some potentially noisy observations of $f(x)$. This is made possible by employing a prior distribution over the function $f(x)$. As shown in section 4.1, a GP is essentially assuming a Gaussian distribution over functions.

4.2.1 Bayesian Linear Regression

We consider again the linear regression model from chapter 3. However, we assume a more general setting, where the data generating process does not need to be a time series process. We denote the mean function with $f(x)$ instead of $\mu(t)$ and Y_i is again a noisy observations of $f(x_i)$, where the additive error E_i does not necessarily need to arrive from a time series process $E(t)$. We obtain the following data generating model:

$$f(x_i) = x_i^\top \beta, \quad Y_i = f(x_i) + E_i, \quad (i = 1, \dots, n)$$

with $x_i \in \mathbb{R}^p$ being again the input vector and $\beta \in \mathbb{R}^p$ is the vector with the regression coefficients.

In matrix form:

$$\mathbf{Y} = X\beta + \mathbf{E}$$

Where $\mathbf{Y} = [Y_1, \dots, Y_n]^\top$ is the observed data, $X = [x_1, \dots, x_n]^\top \in \mathbb{R}^{n \times p}$ is the design matrix. We assume again gaussian but potentially correlated errors $\mathbf{E} = [E_1, \dots, E_n]^\top$:

$$\mathbf{E} \sim \mathcal{N}(0, \Sigma_n)$$

If \mathbf{E} is an ARMA process with gaussian innovations, \mathbf{E} being a sum of innovations, will also have gaussian distribution and this assumption is thus valid.

The likelihood of the observations \mathbf{Y} given X and β is then:

$$p(\mathbf{Y}|X, \beta) = \frac{1}{((2\pi)^{n/2} \sqrt{\det(\Sigma_n)})} \exp\left(-\frac{1}{2}(y - X\beta)^\top \Sigma_n^{-1}(y - X\beta)\right) = \mathcal{N}(X\beta, \Sigma_n)$$

The Bayesian approach differs from the one in chapter 3 in that we assume a prior distribution over the regression coefficients β , based on what we believe are likely values for the coefficients. To stay in the realm of gaussian processes the prior has to be gaussian and we choose:

$$p(\beta) = \mathcal{N}(0, \Sigma_p)$$

Given our observations \mathbf{Y} we can use Bayes' theorem to calculate the posterior distribution over β :

$$p(\beta|\mathbf{Y}, X) = \frac{p(\mathbf{Y}, \beta|X)}{p(\mathbf{Y}|X)} = \frac{p(\mathbf{Y}|X, \beta)p(\beta)}{p(\mathbf{Y}|X)}$$

One approach is to just plug in the expressions for $p(\mathbf{Y}|X, \beta)$ and $p(\beta|\mathbf{Y}, X)$ from above, with:

$$p(\mathbf{Y}|X) = \int p(\mathbf{Y}|X, w)p(w)dw = \mathcal{N}(0, X\Sigma_p X^\top + \Sigma_n)$$

Or it can be helpful to combine the coefficients and the observations into a single random vector with multivariate normal distribution:

$$\begin{bmatrix} \mathbf{Y} \\ \beta \end{bmatrix} = \begin{bmatrix} X \\ I_p \end{bmatrix} \begin{bmatrix} \beta \\ E \end{bmatrix} \sim \mathcal{N} \left(\begin{bmatrix} 0 \\ 0 \end{bmatrix}, \begin{bmatrix} X\Sigma_p X^\top + \Sigma_n & X\Sigma_p \\ \hline \Sigma_p X^\top & \Sigma_p \end{bmatrix} \right) = p(\mathbf{Y}, \beta) \quad (4.2.1.1)$$

with $\Sigma_p X^\top + \Sigma_n \in \mathbb{R}^{n \times n}$ and $\Sigma_p X^\top \in \mathbb{R}^{p \times n}$.

To find now the posterior distribution $p(\beta|\mathbf{Y})$ one can use the well known rules for deriving conditional distributions for jointly Gaussian random vectors, which will be presented quickly. Let's say that $\mathbf{A} \sim \mathcal{N}(\mu_A, \Sigma_{AA})$ and $\mathbf{B} \sim \mathcal{N}(\mu_B, \Sigma_{BB})$ are Gaussian random vectors with the following joint distribution:

$$p(\mathbf{A}, \mathbf{B}) = \mathcal{N}\left(\begin{bmatrix} \mu_A \\ \mu_B \end{bmatrix}, \begin{bmatrix} \Sigma_{AA} & \Sigma_{AB} \\ \Sigma_{BA} & \Sigma_{BB} \end{bmatrix}\right) \quad (4.2.1.2)$$

The distribution $p(\mathbf{B}|\mathbf{A} = a)$ is also normally distributed with mean $\bar{\mu}$ and covariance $\bar{\Sigma}$ of the following form:

$$\bar{\Sigma} = \Sigma_{BB} - \Sigma_{BA}\Sigma_{AA}^{-1}\Sigma_{AB} \quad \bar{\mu} = \mu_B + \Sigma_{BA}\Sigma_{AA}^{-1}(a - \mu_A) \quad (4.2.1.3)$$

Using this rule we obtain for the mean and covariance of $p(\beta|\mathbf{Y} = y) \sim \mathcal{N}(\bar{\mu}, \bar{\Sigma})$:

$$\bar{\Sigma} = \Sigma_p - \Sigma_p X^\top (X \Sigma_p X^\top + \Sigma_n)^{-1} X \Sigma_p \quad \bar{\mu} = \mu_\beta + \Sigma_p X^\top (X \Sigma_p X^\top + \Sigma_n)^{-1} y$$

and using Woodbury matrix identity we can further simplify:

$$\bar{\Sigma} = (X^\top \Sigma_n^{-1} X + \Sigma_p^{-1})^{-1} \quad \bar{\mu} = \bar{\Sigma} X^\top \Sigma_n^{-1} y$$

Deriving the predictive distribution of $f^* := f(x^*)$ at x^* given our observations is then straight forward:

$$p(f^*|\mathbf{Y}) = \mathcal{N}(x^{*\top} \bar{\mu}, x^{*\top} \bar{\Sigma} x^*) \quad (4.2.1.4)$$

One can also use the rules for conditioning to directly derive $f^*|\mathbf{Y}$. Similarly to before we can write the joint distribution $p(\mathbf{Y}, f^*)$:

$$\begin{bmatrix} \mathbf{Y} \\ f^* \end{bmatrix} = \begin{bmatrix} X \\ x^* \end{bmatrix} \beta + \begin{bmatrix} I_n \\ 0 \end{bmatrix} E \sim \mathcal{N}\left(\begin{bmatrix} 0 \\ \vdots \\ 0 \\ 0 \end{bmatrix}, \begin{bmatrix} X \Sigma_p X^\top + \Sigma_n & X \Sigma_p x^* \\ \hline x^{*\top} \Sigma_p X^\top & \Sigma_p \end{bmatrix}\right) = p(\mathbf{Y}, \beta) \quad (4.2.1.5)$$

The expression in 4.2.1.4 can then be derived similarly to before using the rules for conditioning of gaussian random vectors described in 4.2.1.3.

4.2.2 Gaussian Process Regression

By abandoning the parameters β , in Gaussian process regression we are always directly aiming for the predictive distribution of $f^* := f(x^*)$ at x^* given our observations. In order to derive $f^*|\mathbf{Y}$ we will again consider the Bayesian linear regression example from the last section.

We chose a gaussian prior over the regression coefficients and for the prior distribution $p(\mathbf{Y})$ we had:

$$\mathbf{Y} \sim \mathcal{N}(0, \Sigma_p X^\top + \Sigma_n)$$

Alternatively we can assume a distribution over \mathbf{Y} as a function of x :

$$\mathbf{Y}(x) \sim GP(0, k(x, x'))$$

where $k(x, x')$ needs to be chosen such that for an input X we obtain $K_{XX} = \Sigma_p X^\top + \Sigma_n$ to obtain $y^*|\mathbf{Y}$

We have seen that the likelihood of the observations Y given X and β is given by:

$$\mathbf{Y}|X, \beta \sim \mathcal{N}(X\beta, \Sigma_n)$$

If we assume now

If we assume \mathbf{Y} as a random function of x we can write:

$$\mathbf{Y}(x) \sim GP(X\beta, K_{YY})$$

where K_{YY} needstobe

Appendix A

Complementary information

Additional material. For example long mathematical derivations could be given in the appendix. Or you could include part of your code that is needed in printed form. You can add several Appendices to your thesis (as you can include several chapters in the main part of your work).

A.1 Including R code with verbatim

A simple (rather too simple, see [A.2](#)) way to include code or *R* output is to use `verbatim`. It just prints the text however it is (including all spaces, “strange” symbols,...) in a slightly different font.

```
## loading packages
library(RBGL)
library(Rgraphviz)
library(boot)
```

```
## global variables
X_MAX <- 150
```

```
    This allows me to put as many s p a c e s as I want.
I can also use \ and ' and & and all the rest that is usually only
accepted in the math mode.
```

```
I can also make as
                many
            line
        breaks as
I want... and
                where I want.
```

But really recommended, much better is the following:

However, it is much nicer to use the *listings* package to include R code in your report. It allows you to number the lines, color the comments differently than the code, and so on. All the following is produced by simply writing `\lstinputlisting{Pictures/picture.R}` in your L^AT_EX “code”:

```
or \lstinputlisting{/u/maechler/R/Pkgs/sfsmisc/R/ellipse.R} :
```

[illegible]

A.3 Using Sweave (or knitr) to include R code (and more) in your report

The easiest (and most elegant) way to include R code and its output (and have all your figures up to date with your report) is to use Sweave—or the **knitr** R package with even more possibilities.

Search the web to find lots of intro material on how to use Sweave or **knitr** ([on Wikipedia](#)).

Appendix B

Yet another appendix....

B.1 Description

Something details.

Something else other definition.

B.2 Tables

Refer to Table [B.1](#) to see a left justified table with caption on top.

Table B.1: Results.

Student	Grade
Marie	6
Alain	5.5
Josette	4.5
Pierre	5

Appendix C

2nd Appendix: More sophisticated R code listing

Chapter-wise listing of parts of R code, using

- `firstline=n1`
- `lastline=n2`
- `title=<text>`

e.g., for the first example below

```
\lstinputlisting[firstline=1,lastline=20,  
                  title= \texttt{ellipse.R}]{ellipse.R}
```

and the second example

```
\lstinputlisting[firstline=20,lastline=40,  
                  title=\texttt{ellipse.R}]{ellipse.R}
```

C.1 Chapter 5

```
1 ellipsePoints ← function(a,b, alpha = 0, loc = c(0,0), n = 201,  
2                       keep.ab.order = FALSE)  
3 {  
4   ## Purpose: ellipse points, radially equispaced, given geometric par.s  
5   ## -----  
6   ## Arguments: a, b : length of half axes in (x,y) direction  
7   ##             alpha: angle (in degrees) for rotation  
8   ##             loc  : center of ellipse  
9   ##             n    : number of points  
10  ## -----  
11  ## Author: Martin Maechler, Date: 19 Mar 2002  
12  
13  stopifnot(is.numeric(a), is.numeric(b))  
14  reorder ← a < b && keep.ab.order  
15  B ← min(a,b)  
16  A ← max(a,b)  
17  ## B <= A  
18  d2 ← (A-B)*(A+B) ## = A^2 - B^2  
19  phi ← 2*pi*seq(0,1, len = n)  
20  sp ← sin(phi)
```

ellipse.R

```
1  sp <- sin(phi)
2  cp <- cos(phi)
3  r <- a*b / sqrt(B^2 + d2 * sp^2)
4  xy <- r * if(reorder) cbind(sp, cp) else cbind(cp, sp)
5  ## xy are the ellipse points for alpha = 0 and loc = (0,0)
6  al <- alpha * pi/180
7  ca <- cos(al)
8  sa <- sin(al)
9  xy %*% rbind(c(ca, sa), c(-sa, ca)) + cbind(rep(loc[1],n),
10                                              rep(loc[2],n))
11 }
```

ellipse.R

Epilogue

A few final words.

Declaration of Originality

The signed declaration of originality is a component of every semester paper, Bachelor's thesis, Master's thesis and any other degree paper undertaken during the course of studies, including the respective electronic versions.

Lecturers may also require a declaration of originality for other written papers compiled for their courses.

I hereby confirm that I am the sole author of the written work here enclosed and that I have compiled it in my own words. Parts excepted are corrections of form and content by the supervisor .

Title of work (in block letters):

Authored by (in block letters):

For papers written by groups the names of all authors are required.

Name(s):

First name(s):

Muster	Student

With my signature I confirm that

- I have committed none of the forms of plagiarism described in the Citation etiquette information sheet.
- I have documented all methods, data and processes truthfully.
- I have not manipulated any data.
- I have mentioned all persons who were significant facilitators of the work .
- I am aware that the work may be screened electronically for plagiarism.
- I have understood and followed the guidelines in the document *Scientific Works in Mathematics*.
